#### Abstract

This project was funded under the Federal Aid in Sport Fish Restoration Program utilizing state fishing license money and federal grant funds derived from federal excise taxes on fishing tackle and other fishing related expenditures. Funds from the Sport Fish Restoration Program are used for fisheries management and research, aquatic education, and boating access facilities. The program is administered cooperatively by the N.C. Wildlife Resources Commission and the U.S. Fish and Wildlife Service.

Abstract. Monitoring of the Neuse River is necessary to ensure regulations are appropriate and beneficial to our angling constituency. Sport fish were collected from the Neuse River with boatmounted electrofishing gear October through November 2020. Largemouth Bass Micropterus salmoides, Bluegill Lepomis macrochirus, and Redear Sunfish L. microlophus size structure, relative abundance, and condition were assessed. Other sport fish species were collected but not in sufficient abundance to warrant analysis. Largemouth Bass abundance was near average when compared to previous Neuse River samples, with much of the sample consisting of ages 0 and 1. Bluegill abundance in the Neuse River appeared to indicate that fish are reproducing in a manner expected for a healthy population. Memorable- and trophy-length Bluegill were not observed; however, this seems to be typical for the Neuse River. Redear Sunfish in the Neuse River were observed up to memorable-length, although the low sample size merits caution when analyzing this data set. Condition factors suggest adequate forage availability for all three species. The declining abundance of Redbreast Sunfish and Pumpkinseed is a notable trend. Declines could be attributed to Flathead Catfish predation as the abundance of these two sunfish species has decreased since the establishment of Flathead Catfish in the Neuse River. Lastly, the decrease in abundance of Largemouth Bass between age 2 and 3 was evidence of fish kills associated with Hurricane Florence in 2018.

The Neuse River begins near Raleigh, NC, 376 km from the mouth where it joins the Pamlico Sound. The source of the Neuse River in the coastal plain originates from a hypolimnetic discharge from Falls Lake Dam. At its origin, the Neuse River can be clear to turbid depending on rainfall and sediment loading. The Neuse River gradually converts to a blackwater system typical of coastal North Carolina rivers. Anglers fishing this river target freshwater, anadromous, and marine fish species. The lower 64 km of the Neuse River experiences salinity influences from the Pamlico Sound, and marine species are commonly observed. The rest of the Neuse River basin supports a warmwater fish assemblage that provides a recreational fishery valued around $\$ 4,000,000$ annually (Rundle et al. 2004). The majority of the freshwater fishing activity targets Largemouth Bass Micropterus salmoides, sunfish Lepomis spp., Black Crappie Pomoxis nigromaculatus, and catfish Ictalurus spp.

Hurricane-related fish kills have been well documented throughout the southeastern United States (Tabb and Jones 1962, Alford et al. 2009, Vrancken and O’Connell 2010) and in North Carolina (McCargo et al. 2008, Thomas and Dockendorf 2009, Ricks and Rachels 2015). These widespread kills are often a result of increased biological oxygen demand that causes a decrease in dissolved oxygen. The increase in biological oxygen demand is usually caused by decomposition of high inputs of natural material, re-suspension of bottom sediments, or wastewater system overflows (Bales and Childress 1996, Bales and Waters 2004). The most significant hurricanes to impact the Neuse River basin in recent years were Hurricane Irene (2011), Hurricane Matthew (2016), and Hurricane Florence (2018). While Hurricane Irene caused extensive fish kills in the Neuse River basin, hurricanes Matthew and Florence were responsible for isolated fish kill events.

In addition to hurricane-related fish kills, non-native fish introductions have become a conservation concern for the Neuse River. The primary non-native introduction that has impacted the Neuse River is the establishment of Flathead Catfish Pylodictis olivaris. Flathead Catfish compete with and predate directly on native fish species (Pine et al. 2005; Baumann and Kwak 2011).

Any significant changes to the fish assemblage in the Neuse River could have impacts on recreational angling success. Therefore, it is important for fishery managers to monitor changes and shift management actions accordingly. Survey objectives are to document recovered populations and establish a baseline to allow for comparison with future surveys. In addition, impacts to Neuse River sport fish populations from invasive Flathead Catfish will also be documented.

## Methods

Sport fish were collected with boat-mounted electrofishing gear (Smith Root 7.5 GPP; 5000-8000 W pulsed DC; 4-6 amps) during daylight hours between October 10, 2020 and November 10, 2020. Sites targeted either Largemouth Bass only or sport fish, which consisted of all sport fish species observed excluding catfishes. Twenty-five (12 tributary and 13 mainstem) sport fish sites and 26 (17 tributary and 9 mainstem) Largemouth Bass-only sites were surveyed (Figure 1). Sampling sites were along shoreline transects and were 15 minutes in duration for sport fish sites and 30 minutes in duration for Largemouth Bass-only sites. For each site, target species were netted as they were encountered and held in a livewell. Upon
completion of the site, all fish collected were enumerated, measured for total length (TL, mm), and weighed (g). Up to 10 Largemouth Bass per $25-\mathrm{mm}$ length increment were sacrificed for sagittal otolith extraction and age determination. Otolith annular rings were first enumerated in whole view under a dissecting microscope. Otoliths determined to be age 3 or older were divided in half, sanded, and polished. Otolith annular rings were then enumerated using fiberoptic light directed across the polished section of the otolith (Hoyer et al. 1985; Buckmeier and Howells 2011). Each otolith was read by two readers. Any discrepancies between the two readers were resolved with a third read in concert.

Relative abundance of Largemouth Bass, Bluegill L. macrochirus, and Redear Sunfish L. microlophus was expressed as the number of fish collected per electrofishing hour and was indexed as catch-per-unit-effort (CPUE; fish/h). Largemouth Bass CPUE was reported for combined Largemouth Bass-only sites and sport fish sites. Relative abundance was reported for multiple length categories. Length categories were defined for Largemouth Bass as stock-length (200-299 mm ), quality-length (300-379 mm ), preferred-length ( $380-509 \mathrm{~mm}$ ) and memorablelength (510-629 mm). Bluegill length categories were defined as stock-length ( $80-149 \mathrm{~mm}$ ), quality-length (150-199 mm), preferred-length (200-249 mm) and memorable-length (250-300 mm ). Redear Sunfish length categories were defined as stock-length ( $100-179 \mathrm{~mm}$ ), qualitylength (180-299 mm), preferred-length (230-279 mm ) and memorable-length (280-329 mm). Size structures of the Largemouth Bass, Bluegill, and Redear Sunfish populations were evaluated with length frequency histograms as well as proportional size distribution (PSD; Anderson and Newman 1996; Guy et al. 2007). Largemouth Bass, Bluegill, and Redear Sunfish condition factors were assessed with the relative weight index ( $W_{r}$ ) developed by Wege and Anderson (1978). For Largemouth Bass, mean length-at-age was calculated after applying a length-at-age key to the entire sample. The Poisson GLM mortality estimator was used to calculate total instantaneous mortality using the peak plus 1 observed year class abundance ( $Z$; Nelson 2019).

## Results

A total of 403 Largemouth Bass was collected from the Neuse River; 276 Largemouth Bass were stock-length or greater (Table 1). Relative abundance was highly variable between transects (range 0-56 fish/h), and mean CPUE was 18.42 fish/h (SE = 2.22). Substock-length and stock-length Largemouth Bass were most abundant (overall CPUE 11.9 fish/h) and constituted $60 \%$ of the sample (Figure 2). Largemouth Bass lengths ranged from 66 mm to 597 mm , and $23 \%$ were at or above the minimum length limit ( 356 mm ; Figure 3). Mean length for Largemouth Bass was 266 mm (SE = 6.1). PSD for Largemouth Bass was 57\%. PSDQ-p and PSDp-m were similar at $28 \%$ and $24 \%$ while PSD $_{\mathrm{s}-\mathrm{Q}}$ was higher ( $43 \%$; Figure 4). Mean relative weight for Largemouth Bass was 98 ( $\mathrm{SE}=0.6$ ) and was similar across all length categories (Stock-length $W_{r}$ $=94$, SE = 0.7; Quality-length $W_{r}=98, \mathrm{SE}=1.0$; Preferred-Length $W_{r}=100, \mathrm{SE}=1.0$; Memorable-length $W_{r}=98, S E=1.8$; Figure 5). Largemouth Bass ages ranged from 0 to 10 (Table 2). The most abundant ages were ages $0-2$, which constituted $78 \%$ of the sample (Figure 6). The Poisson GLM mortality estimator yielded an instantaneous mortality rate (Z) of 0.47 (SE $=0.07)$, which corresponds to a $37 \%$ annual discrete mortality rate $(A)$.

A total of 423 Bluegill was collected from the Neuse River (Table 3). Relative abundance of Bluegill was highly variable between transects (ranged 0-302 fish/h). Mean CPUE was 61.7 fish/h (SE = 13.4) with quality-length being the highest in abundance ( 30.3 fish/h). Bluegill lengths ranged from 52 mm to 234 mm , and the majority of the sample ( $72 \%$ ) was between 125 mm and 200 mm . Mean length for Bluegill was 152 mm ( $\mathrm{SE}=1.6$ ). Bluegill PSD was $56 \%$. $\mathrm{PSD}_{\mathrm{s}-\mathrm{Q}}$, PSD ${ }_{\text {Q-p, }}$ and $P_{S D}$ P-m were $44 \%, 49 \%$, and $7 \%$, respectively. Mean relative weight for Bluegill was 86.1 ( $\mathrm{SE}=0.6$ ) and was similar from stock- to preferred-length (Stock $W_{r}=84, \mathrm{SE}=1.1$; Quality $W_{r}=88, \mathrm{SE}=0.6$; Preferred $W_{r}=88, \mathrm{SE}=1.4$ ).

In the 2020 Neuse River sport fish sample, 159 Redear Sunfish were collected. Relative abundance of Redear Sunfish was variable between transects (range 0-75 fish/h) and mean CPUE was 23.5 fish/h (SE = 5.0). Redear Sunfish lengths ranged from 46 mm to 274 mm and displayed a peak at 175 mm . Mean length for Redear Sunfish was 187 mm (SE = 3.1). Redear Sunfish PSD was $61 \%$. PSD ${ }_{\text {s-Q }}$, PSD ${ }_{\text {Q-P, }}$ and PSDP-m were $39 \%, 47 \%$, and $13 \%$, respectively. Mean relative weight for Redear Sunfish was 89.6 ( $\mathrm{SE}=0.8$ ).

Black Crappie ( $\mathrm{N}=16$ ), Warmouth L. gulosus ( $\mathrm{N}=9$ ), Redbreast Sunfish L. auritus ( $\mathrm{N}=8$ ), Pumpkinseed L. gibbosus ( $\mathrm{N}=7$ ), Chain Pickerel Esox niger ( $\mathrm{N}=4$ ), and White Perch Morone americana ( $\mathrm{N}=1$ ) were also collected in insufficient numbers to warrant further analysis.

## Discussion

The high abundance of age-0, age-1, and age-2 Largemouth Bass in the Neuse River showed evidence of recent successful spawns. The abundance of Largemouth Bass age 3-10 showed little variation, ranging from $5.7 \%$ to $0.5 \%$, which explains the low mortality rate reported. Condition factors suggested adequate forage availability. As the stock- and substocklength fish recruit into the fishery, the population will likely provide improved angling opportunities for harvestable Largemouth Bass. The decrease in abundance of Largemouth Bass from age 2 to age 3, was evidence of isolated fish kills associated with Hurricane Florence in 2018. Because fish kills were isolated, however, the low but persistent age-classes from age 3 to age 10 suggests Largemouth Bass were able to survive in unaffected areas.

Bluegill in the Neuse River appeared to be in abundances that indicated fish were reproducing in a manner expected for a healthy population. There were no signs of low recruitment in the length frequency, and fish reached preferred length. The lack of memorableand trophy-length Bluegill suggested growth rates were less than what is expected for healthy populations or that food availability was affecting growth rates. However, relative weights indicated that overall body condition was acceptable; therefore, food availability was likely not limited. Furthermore, surveys conducted since 2002 did not contain memorable- or trophylength fish in the Neuse River, so these results seem to be typical for Neuse River Bluegill. Collecting age data during future surveys should be considered to evaluate mortality for Bluegill in the Neuse River.

Redear Sunfish in the Neuse River were observed up to memorable length, although the low sample size merits caution when analyzing this data set. Future surveys should attempt to collect more Redear Sunfish to better describe the population.

Results from this survey indicate abundances of Redbreast Sunfish and Pumpkinseed have decreased in recent years. In 1994, Redbreast Sunfish were almost equal to Bluegill (Kornegay
et al. 1994), yet Redbreast Sunfish were much less abundant than Bluegill in 2020. In 2003, Pumpkinseed CPUE ( 68.4 fish/h; unpublished data) was 66 times higher than Pumpkinseed CPUE observed in 2020 ( 1.0 fish $/ \mathrm{h}$ ). These declines in abundance could likely be attributed to Flathead Catfish predation, as abundances of these two sunfish species have decreased since the establishment of Flathead Catfish in the Neuse River and introduced Flathead Catfish have been shown to impact native fish communities (Pine et al. 2005, Baumann and Kwak. 2011).

## Management Recommendations

1. Maintain current harvest limits. Largemouth Bass harvest in these rivers is regulated by a minimum size limit of 356 mm ( 14 in ) with a creel limit of five fish per day, with 2 fish allowed under the minimum size limit. Sunfish harvest is regulated by a creel limit of 30 sunfish per day in combination with no more than 12 Redbreast Sunfish L. auritus.
2. Assess sportfish abundance and growth rates by surveying the Neuse River sportfish populations by 2025.
3. Promote these fisheries when opportunities are available via biological presentations at fishing club meetings, public forums, and website updates.
4. Consider collecting age data from sunfish during the next Neuse River sport fish survey.
5. Continue to employ the NCWRC Hurricane Response Plan.
6. Conduct a Neuse River Creel Survey. Creel data are more than 10 years old; current creel information would inform management decisions.

## Acknowledgments

We thank Kevin Dockendorf, Jeremy McCargo, and Chad Thomas for their review of previous drafts which were valued and significantly improved the quality of this report.

** Prior to 2014 if sites on the Trent River were included in Neuse River reporting. After 2014 Trent River sites were summarized independently when
sampled.

FIGURE 1. Boat electrofishing sites for the 2020 Neuse River sport fish survey.

FIGURE 2. Total catch per unit effort (CPUE) for Largemouth Bass, Bluegill, and Redear Sunfish by PSD increments collected during the 2020 central coastal rivers sport fish survey.

FIGURE 3. Length distribution for Largemouth Bass, Bluegill, and Redear Sunfish collected via electrofishing in the Neuse River, 2020.

FIGURE 4. PSD values for Largemouth Bass, Bluegill, and Redear Sunfish collected via electrofishing in the Neuse River, 2020.

FIGURE 5. Mean relative weight by PSD length category for Largemouth Bass, Bluegill, and Redear Sunfish. Error bars represent one standard error. The dotted line at $W_{r}=100$ denotes the $75^{\text {th }}$ percentile of weights at given length categories for each species across its entire range.

FIGURE 6. Age distribution for Largemouth Bass collected via electrofishing in the Neuse River, 2020.
