[^0]Abstract. In spring 2018 and 2019, 279 and 299 Striped Bass Morone saxatilis were collected from the Neuse River spawning grounds via boat electrofishing. Mean daily CPUE was 12.6 fish/h in 2018 and 15.1 fish/h in 2019. Abundance of age-6 and older fish was 3.4 fish/hour in 2018 and 1.3 fish/h in 2019. Growth continued to be rapid, as age-3 mean total length was 485 mm for males and 502 mm for females in 2018, and 489 mm for males and 517 mm for females in 2019. In 2018, eight year-classes were present for males (age 2-9) and seven year-classes were present (age 39) for females. The 2014 and 2015 year-classes were the most abundant year-classes in 2018, representing 61.5\% of the sample. In 2019, seven year-classes were present for males and females (age 3-9). The 2016 year-class was the most abundant in 2019 for both males and females. Annual mortality continued to remain high at $45 \%$ in 2018 and $50 \%$ in 2019. Hatchery contribution was $77.6 \%$ in 2018 and $89.8 \%$ in 2019. In 2018, the length-frequency peak of non-hatchery Striped Bass at 475 mm suggests recruitment of a natural year-class in 2015. This wild 2015 cohort was evident in the size structure data from 2019, with a peak at 525 mm . Overall, the low abundance and truncated age-distribution support catch-curve estimates indicating high spawning stock mortality, while results of parentage-based tagging suggest a high proportion of the spawning stock is hatchery-reared. Cooperation with NC Division of Marine Fisheries will be required to improve the stock as the population is spatially extant in joint and coastal waters for most of the year.

The North Carolina Wildlife Resources Commission (NCWRC) conducts annual spawning stock assessments of migratory Striped Bass Morone saxatilis populations utilizing inland waters within the Central Southern Management Area (CSMA). The CSMA management unit is defined as all internal coastal, joint and contiguous inland waters of North Carolina south of a line from Roanoke Marshes Point across to Eagle Nest Bay in Dare County, to the South Carolina state line (NCDENR 2013). The goal of CSMA Striped Bass assessments is to monitor Striped Bass populations migrating to the spawning grounds within the Tar, Neuse, and Cape Fear rivers, and to recommend and evaluate management actions for stock improvement.

Striped Bass in the CSMA are considered a stock of concern by the North Carolina Division of Marine Fisheries (NCDMF). The need for conservative management efforts is supported by "truncated size and age distributions, low overall abundance, and an absence of older fish in spawning ground surveys" (NCDENR 2013). Rachels and Ricks (2015) outlined that cryptic mortality (undocumented fishing mortality) was a major concern for managers attempting to reduce the high mortality experienced by Striped Bass in the Neuse River. Additionally, Rachels and Ricks (2016) observed that gillnet effort (number of nets set annually) in the lower Neuse River commercial fishery was a good predictor of Striped Bass mortality the following year.

Spawning stock data collected in inland waters by NCWRC will be combined with NCDMF data collected in joint and coastal waters to develop a comprehensive stock assessment model for Striped Bass within the CSMA. Estimates of fishing mortality rates coupled with analyses of basic population trends are critical for determining the appropriate total allowable harvest of Striped Bass from the CSMA Striped Bass fisheries while still allowing for stock preservation and growth. Development and execution of comprehensive inter-agency fisheries management plans are necessary to support the enhancement of Striped Bass populations within coastal North Carolina for the benefit of recreational and commercial anglers (NCDENR 2013).

In the Neuse River, Striped Bass have been surveyed by NCWRC staff using boat-mounted electrofishing each spring since 1994 to assess spawning stock characteristics. This time series encompasses the 1998 removal of Quaker Neck Dam on the main-stem Neuse River at river kilometer (rkm) 225 that blocked access to Striped Bass spawning habitat upstream of Goldsboro, NC (Burdick and Hightower 2006). Furthermore, in 2017 Milburnie Dam was removed, providing access to spawning habitats upstream to Falls Dam (rkm 376) when flows allow. Analyses of catch data suggest Striped Bass spatial distribution during spawning varies among years since the removal of Quaker Neck Dam.

Due to low spawning stock abundance and limited Striped Bass recruitment, an annual stocking program has occurred on the Neuse River since 1993. From 1994 to 2011, the Roanoke River was the broodfish source. However, since stocking began there has been little improvement in Striped Bass age-structure or mortality (Dycus et al. 2014). In 2012, the stocking program transitioned to Neuse River broodfish to determine if stocking river-specific Striped Bass would result in an increase in spawning stock abundance (e.g., Bulak et al. 2004). Parentage-based tagging techniques also began in 2012, providing the use of discrete genetic markers to evaluate the proportion of hatchery fish in the population. Preliminary assessments in 2012-2015 indicated very little natural reproduction occurred (NCWRC unpublished data), which was also observed by Barwick and Homan (2008). Understanding the contribution of hatchery fish to the Neuse River spawning stock will assist management decisions and assessment of Fishery Management Plan (FMP) objectives.

Prior to October 2018, inland waters in the Neuse River were managed with a 457 mm minimum length limit with a protective slot from 559 mm to 686 mm . In October 2018, a 660 mm minimum length limit was established by rule in inland waters. However, prior to implementation, a proclamation was signed in March 2019 by the NCWRC Executive Director to suspend the existing rules and establish a moratorium on recreational harvest in the Neuse River and all its tributaries below Falls Dam. This decision was made to support a moratorium established by the NCDMF in joint and coastal jurisdictions.

This report documents the annual NCWRC Striped Bass spawning stock survey conducted in the Neuse River in 2018 and 2019. The objective of this spawning stock survey was to quantify Striped Bass spawning stock characteristics by estimating relative abundance, size-structure, age-structure, mortality, and contribution of hatchery fish to the spawning stock.

## Methods

Spawning Stock Assessment. During concurrent sampling for American Shad, NCWRC staff collected Striped Bass in the Neuse River from April 8, 2018 to 19 May 19, 2018 and from April 7, 2019 to May 18, 2019. Directed Striped Bass sampling began in Goldsboro and continued weekly during optimum spawning temperatures $\left(18-22^{\circ} \mathrm{C}\right)$. Additional sites in Goldsboro, Raleigh, and Smithfield were sampled weekly as Striped Bass catches increased (Figure 1). Sampling at all sites was contingent upon adequate streamflow to allow boat access (Table 1). Sampling ceased when Striped Bass spawning appeared complete. Striped Bass were collected using a boat-mounted electrofishing unit (Smith-Root 7.5 GPP). To minimize size selection during sampling, fish were netted as they were encountered, and electrofishing time (seconds) was recorded for each sample site. Mean daily water temperature ( ${ }^{\circ} \mathrm{C}$ ) was recorded at each sample site. Mean daily discharge ( $\mathrm{ft}^{3} / \mathrm{s}$ ) was recorded from the U.S. Geological Survey gaging station (02087500) near Clayton.

Striped Bass were measured for total length (TL; mm) and weight (g). Sex was determined by applying directional pressure to the abdomen toward the vent and observing the presence of milt (male) or eggs (female). To estimate contribution of hatchery fish to the spawning stock using parentage-based tagging (PBT) analysis, a partial pelvic fin clip was removed from Striped Bass until 200 fin clips were collected and archived. Scale samples were also taken from all fish where fin clips were taken. Age assignment was done using a combination of data collected during PBT analyses, with scales read for age determination if the fish was not identified during PBT analyses as a known-aged hatchery fish. For fish without either a scale or a fin clip sample, ages were assigned based on a sex specific age-length key.

Before release, Striped Bass were tagged with an individually numbered internal anchor tag as a cooperative effort with the ongoing NCDMF Striped Bass tagging program (Winslow 2010). Recaptured, tagged Striped Bass were identified by tag number. Recaptures from the current sample year were recorded in the site of capture unless the recapture occurred on the same day as tagging.

All field data were recorded using a Trimble Yuma field computer and archived in the NCWRC BIODE database. Relative abundance of Striped Bass for each sample was indexed by catch per unit effort (CPUE; fish/h). Mean CPUE was calculated for all sampling sites during a calendar week. Site-specific CPUE was analyzed to elucidate spatial differences in spawning
grounds utilization. Daily mean CPUE and peak daily CPUE were calculated to analyze annual trends in abundance. Length-frequency distributions by sex were used to evaluate size structure. Mean lengths at age were calculated for the entire sample following methods described by Bettoli and Miranda (2001). The Chapman-Robson estimator was used to elucidate total instantaneous mortality $(Z)$ following the recommendations of Smith et al. (2012).

Broodfish collections and stocking. Broodfish collections were conducted via boat-mounted electrofishing. Collections were in conjunction with the spawning stock survey with additional sites added to acquire sufficient numbers of broodfish. Broodfish were transported to Edenton National Fish Hatchery for propagation and rearing of juveniles, with the goal of producing 100,000 phase-II (125-200 mm) fingerlings and one million fry. Fin clips for genotyping were collected from all broodfish to allow for future PBT assessments.

Hatchery contribution. Genotyping for PBT analysis was conducted on fin clip samples by the South Carolina Department of Natural Resources (SCDNR) Hollings Marine Lab. Parentagebased tagging analysis was available for year-classes stocked in the Neuse River since 2010. Since a portion of the Neuse River Striped Bass stock may be in age-classes older than 2010, hatchery contribution presented herein should be considered preliminary and finalized data will be addressed completely in a future report.

## Results

2018 spawning stock assessment. Field staff collected 279 Striped Bass in 2018. Weekly mean (SE) CPUE was 13.0 (1.6) fish/h (Table 2). The peak in weekly mean CPUE was 18.2 (2.4) fish/h, occurring the week of April 29, 2018 with water temperatures measuring $18.3^{\circ} \mathrm{C}$ (Table 2). Due to low water levels limiting access to the Raleigh area of the Neuse River, sampling occurred less frequently ( 2.06 h of effort) than the Goldsboro area (10.3 h of effort) or Smithfield/Clayton area (8.9 h of effort). Despite comparable effort in Goldsboro (10.3 h) and the Smithfield/Raleigh area ( 10.9 h ), $60 \%$ of the total sample was collected in Smithfield/Raleigh sites with the majority of those fish (88\%) coming from the Smithfield/Clayton area. Total CPUE upstream of the Goldsboro sampling sites was 15.0 fish/h, compared to 10.5 fish/h observed in the Goldsboro sites.

Age assignment for 272 Striped Bass was conducted using PBT data. Using a sex specific age-length-key, 87 Striped Bass were assigned ages (Tables 3 and 4). Male Striped Bass were represented by eight year-classes (ages 2-9) with the 2015 year-class (age 3) dominating the electrofishing catch by comprising $39 \%$ of the total sample. Age- 4 males were the second most abundant cohort and contributed $27 \%$ to the total sample (Tables 3 and 4). Males age-6+ accounted for $13.7 \%$ of the total sample (Table 3 ) and $16.4 \%$ of the male sample (Table 4 ). Female Striped Bass were represented by seven year-classes (ages 3-9) with the 2013 and 2015 year-class (age 3 and age 5) comprising 41.4\% of the female sample (Table 4). Females age-6+ accounted for $6.4 \%$ of the total sample (Table 3) and $39.6 \%$ of the female sample (Table 4).

Male Striped Bass in Spring 2018 ranged from 259-768 mm, with the peak occurring in the $475-500 \mathrm{~mm}$ size-class. The male size distribution was slightly left skewed (Figure 2). The peak size-class corresponded with age-3 males, which had a mean length of 485 mm and was the most abundant age-class (Tables 4 and 5). Females ranged 475-858 mm TL. The peak size-class
was at 725 mm , however age 3 and age 5 were the most abundant age-classes, suggesting the peak at 725 mm consisted of several overlapping year classes (Tables 4 and 6).

The Chapman-Robson biased corrected method estimated mortality $Z=0.60$ ( $\mathrm{SE}=0.07$ ), which corresponds to a $45 \%$ annual mortality rate ( $A$; Table 7).

2019 spawning stock assessment. In 2019, 299 Striped Bass were collected via electrofishing (Table 2). Weekly mean (SE) CPUE was 16.1 (3.2) fish/h (Table 2). The peak in weekly mean CPUE was 29.0 (8.7) fish/h, occurring the week of April 21, 2019 with water temperatures measuring $18.1^{\circ} \mathrm{C}$ (Table 2). Peak Striped Bass catch occurred April 25, 2019 with 29 fish (CPUE $=136.7$ fish/h) collected near Raleigh. The 2019 sampling season effort was variable across sampling areas throughout the sampling period. Total sampling effort was similar downstream from Goldsboro ( 9.27 fish/h) and upstream from Goldsboro ( 9.95 fish/h). However, $91.6 \%$ of the total sample was collected from the sites above Goldsboro. Total CPUE in upper sampling sites was 27.5 fish/h, compared to 2.7 fish/h in lower sites.

A total of 353 Striped Bass were assigned ages using PBT data, and 23 fish were aged with scales. Using a sex specific age-length-key, 78 Striped Bass were assigned ages (Tables 3 and 4). Male Striped Bass were represented by seven year-classes (ages 3-9) with the 2016 year-class (age 3) dominating the electrofishing catch by comprising $55.7 \%$ of the total sample (Table 4). Age-4 males were the second most abundant cohort and contributed $23.6 \%$ to the total sample (Table 3). Males age-6+ accounted for $8.3 \%$ of the total sample (Table 3) and $11.4 \%$ of the male sample (Table 4). Female Striped Bass were represented by seven year-classes (ages 3-9), with the 2016 year-class (age 3 ) comprising $46.2 \%$ of the female sample and $11.6 \%$ of the total sample (Tables 3 and 4). Females age-6+ accounted for $2.8 \%$ of the total sample (Table 3) and $11.8 \%$ of the female sample (Table 4).

Male Striped Bass in Spring 2019 ranged from 448-803 mm, with the peak occurring in the $450-525 \mathrm{~mm}$ size-class. The male size distribution was left skewed (Figure 2). The peak sizeclass corresponded with age-3 males, which had a mean length of 489 mm and was the most abundant age-class (Tables 4 and 5). Females ranged 488-795 mm TL, with the peak occurring in the 500-575 mm size-class (Figure 2). The peak size-class corresponded with age-3 females, which had a mean length of 517 mm (Tables 4 and 6 ) and were the most abundant age-class.

The Chapman-Robson biased corrected method estimated mortality $Z=0.70$ (SE = 0.06), which corresponds to a $50 \%$ annual mortality rate ( $A$; Table 7).

2018 broodfish collections and stocking. Broodfish collections consisted of seven females and 20 males that were collected via electrofishing and transported to the Edenton National Fish Hatchery. Broodfish were euthanized after spawning was complete. Fin clip samples were provided to the SCDNR Hollings Marine Laboratory to determine hatchery or wild origin for future sampling collections containing the 2018 year-class. Hatchery-reared progeny were moved to ponds for grow-out to phase-II sizes. Due to projected surplus in phase-II fingerlings, phase-I fish (25-50 mm TL) were stocked in Upper Broad Creek, a tributary of the Neuse River at Blackbeard's Marina ( $\mathrm{n}=96,900$ fish) on June 8 (Table 8). Phase-I stockings were not genetically distinct from Bridgeton phase-II stockings; therefore, future genetic sampling will not be able to differentiate between these phase-I and phase-II stocking events. Phase-II stockings consisted of two distinct batches, an upriver batch stocked between November 1 and December 7 at Cox's Ferry BAA near Princeton ( $n=42,881$ fish) and a stocking at the Bridgeton BAA in Bridgeton between November 14 and December 13 ( $n=43,675$ fish; Table 5). On May 4,

670,464 fry were stocked into the Neuse River at Kinston ( $\mathrm{n}=521,472$ fish) and at Bridgeton ( n $=148,992$ fish). The fry stockings at Kinston and Bridgeton were genetically distinct.

2019 broodfish collections and stocking. Broodfish collections consisted of 24 females and 39 males that were collected via electrofishing and transported to Edenton National Fish Hatchery. Broodfish were euthanized after spawning was complete. Fin clip samples were provided to the SCDNR Hollings Marine Laboratory to determine hatchery or wild origin for future sampling collections containing the 2019 year-class. Hatchery-reared progeny were moved to ponds for grow-out to phase-II sizes. Phase-II stockings consisted of two distinct batches, an upriver batch stocked between October 29 and November 6 at the Goldsboro BAA in Goldsboro ( $\mathrm{n}=37,154$ fish) and a stocking at the Bridgeton BAA in Bridgeton between November 11, 2019 and December 05, 2019 ( $\mathrm{n}=48,540$ fish; Table 8). A total of 1,755,000 fry were also stocked in Kinston at the Kinston BAA ( $\mathrm{n}=863,000$ fish ) and in Bridgeton at the Bridgeton BAA ( $\mathrm{n}=892,200$ fish).

2018 hatchery contribution. Genetic analysis of 322 fin clip samples collected in 2018 was completed by the SCDNR Hollings Marine Laboratory. Of the 322 samples, 250 exhibited a genotype indicative of hatchery parentage (78\%). The 2015 hatchery-reared year-class was dominant, providing $23 \%(n=75)$ of the total sample. Hatchery fish by remaining cohort were as follows: 2016 (7\%; n = 22), 2014 (20\%; n = 64), 2013 (11\%; n = 35), 2012 (7\%; n=23), 2011 (5\%; $n=17$ ), and 2010 ( $4 \% ; n=14$ ). The remaining 72 samples ( $22 \%$ ) could not be assigned hatchery parentage and were designated as unknown origin; however, hatchery parentage assignment is not available for pre-2010 year-classes (age 8 and older in 2018). The 72 individuals classified as unknown were either naturally produced or were stocked before 2010 (Figure 3; SCDNR 2019). The peak in the size distribution of non-hatchery Striped Bass at 475 mm suggests that a wild year class was produced in 2015 (Figure 3).

2019 hatchery contribution. Genetic analysis of 226 fin clip samples collected in 2019 was completed by the SCDNR Hollings Marine Laboratory. Of the 266 samples, 203 exhibited a genotype indicative of hatchery parentage ( $89.8 \%$ ). The 2016 hatchery-reared year-class was dominant, contributing $57 \%(n=129)$ of the total sample. Hatchery fish by remaining cohort were represented as follows: 2015 ( $16 \% ; n=36$ ), 2014 ( $6 \% ; n=14$ ), $2013(4 \% ; n=8), 2012(2 \%$; $n=5), 2011(4 \% ; n=8)$, and $2010(1 \% ; n=3)$. The remaining 23 samples ( $10 \%$ ) could not be assigned hatchery parentage and were designated as unknown origin; however, hatchery parentage assignment was not available for pre-2010 year-classes (age 9 and older in 2019). The 29 individuals classified as unknown either hatched in the wild or were stocked before 2010 (Figure 3; SCDNR 2020). The peak in the size distribution of non-hatchery Striped Bass at 525 mm suggests that a wild year class was produced in 2015. (Figure 3).

## Discussion

Results of the 2018 and 2019 Striped Bass spawning stock survey were similar to previous years. The pooled CPUE of Striped Bass in 2018 ( 13 fish/h) and in 2019 ( 15.5 fish/h) was slightly higher than the mean CPUE over time 1994-2019 (11.6 fish/h). No trends in mean daily CPUE were apparent since 1994, despite the removal of Quaker Neck Dam in 1998 and implementation of conservative harvest limits in 2008. The impact of regulation changes in 2018 and 2019 has yet to be formally evaluated. Peak Daily CPUE was higher in 2018 (44.1
fish/h) than the average for the time series ( 38.9 fish $/ \mathrm{h}$ ), and the 2019 values ( 136.7 fish $/ \mathrm{h}$; Table 8) were the highest observed since sampling began. Catch rates from sampling stations in the upper-spawning grounds between Smithfield and Milburnie dam are consistently the highest in the time series. However, because weekly sampling in this area is limited due to logistics, it is likely that portions of the spawning aggregations were missed during years where the peak daily catch rates were lower. For this reason, it should be noted that the increased observed peak daily catch rate in 2019 does not necessarily reflect an increase in relative abundance. Age 6 and older CPUE was 3.4 fish/h in 2018 and the second highest ever recorded; however, in 2019 age- 6 CPUE was 1.3 fish/h. 2018 was one of five years in the time series where age-6 CPUE was 2.2 fish/h or higher. The maximum Striped Bass age observed in 2018 and 2019 was 9 years old. The management objective for the Neuse River is to have an expanded age structure that includes individuals older than age 9; the truncated age-structure is a result of high mortality rates.

Striped Bass in the Neuse River continue to exhibit fast growth that has been observed in previous years (Ricks and Buckley 2018). Mean length for male and female Striped Bass at age 3 was 485 mm and 502 mm in 2018. These Neuse River values are higher than what was observed for the Roanoke River Striped Bass population (Male $=414 \mathrm{~mm}$, Female $=420 \mathrm{~mm}$; Smith and Potoka 2019). Male mean total length in 2018 ( 536 mm ) and 2019 ( 528 mm ) was similar to the mean since sampling began in 1994 ( 534 mm ). Female mean total length in 2018 ( 620 mm ) and 2019 ( 561 mm ) was slightly less than the mean since sampling began ( 630 mm ; Table 7). Mechanisms for fast growth in the Neuse River are poorly understood but could likely be attributed to low Striped Bass density and a large forage base in the system.

Striped Bass mortality in the Neuse River is similar to the total annual mortality that led to the collapse of the Chesapeake Bay Striped Bass stock in the 1970s (Richards and Rago 1999). The collapse of the Chesapeake Bay stock is well documented as having experienced recruitment overfishing that reduced the spawning stock biomass to levels that could not produce dominant year-classes (Richards and Deuel 1987; Richards and Rago 1999). Additionally, Rachels and Ricks (2016) documented that gillnet effort in the lower Neuse River was a good predictor of Striped Bass mortality rates the following year. In March 2019, NCDMF suspended harvest of Striped Bass and the use of gill nets in the Neuse River upstream of the Minnesott Beach Ferry line. The intent of this management action was to reduce Striped Bass mortality and bycatch in commercial gear. This management action has yet to be evaluated.

The high contribution of hatchery-reared fish in 2018 and 2019 suggests stocked fish continue to contribute prodigiously to the Neuse River population. The true contribution of hatchery-reared Striped Bass to the Neuse River population will be unknown until the agestructure is comprised exclusively of fish hatched after the spring of 2010 (the first year PBT techniques were used). Given the current truncated age structure, this will likely occur by 2021. In 2018, 32\% of fish less than 550 mm were non-hatchery. As documented in Ricks and Buckley (2018), this could be the first documented occurrence of wild recruitment since PBT analysis began in 2010. This observation is further supported from angler-caught juvenile Striped Bass fin clip samples from 2016 which revealed $79 \%$ were non-hatchery. Origins of these wild fish were unknown; possibilities include a natural spawning event in either the Neuse or the Tar rivers, or less likely, from the Roanoke River. Nonetheless, PBT analysis indicated 77\% hatchery contribution in the Neuse River spawning grounds electrofishing sample in 2018 (SCDNR 2019).

In 2019, 91\% of the non-hatchery fish that could be aged with scales were 4 years old and were produced in 2015. Hatchery contribution (89.9\%) was high overall in 2019 (SCDNR 2020). While the possibility of 2015 natural recruitment is an encouraging step in terms of population recovery, the Neuse River Striped Bass population is still best described as a hatcherysupported fishery. Current management objectives focus on shifting population recruitment mechanisms toward a self-sustaining population. Evidence of poor natural recruitment has been documented in previous research (Hawkins 1980, Nelson and Little 1991, Barwick and Homan 2008). The determinant of poor wild recruitment has not been identified but includes variables such as egg density and fry transport to nursery areas. Trophic interactions, juvenile nursery habitat, and stock-recruit relationships should be investigated to isolate likely determinants of mortality bottlenecks. However, it is likely that recruitment overfishing is occurring given the high mortality rates present in the Neuse River since at least 1994. Recruitment overfishing has been implicated as a principle factor for Striped Bass recruitment failure (Goodyear et al. 1985; Richards and Deuel 1987; Richards and Rago 1999). Increasing egg deposition on the spawning grounds by increasing the spawning stock biomass and advancing the female age-structure to older individuals may lead to improved natural recruitment (Goodyear 1984). Protecting the female spawning stock through harvest restrictions in conjunction with reduced exploitation will increase SPR to the target (SPR $=0.45$ ) used to create the $F$ biological reference point in the FMP, potentially improving wild recruitment.

## Management Recommendations

1. Continue to evaluate the current harvest moratorium on abundance and hatchery contribution of Striped Bass on the Neuse River spawning grounds.
2. Continue stocking 100,000 phase-II fingerlings utilizing broodfish collected from the Neuse River. Culture two unique genetic batches of phase-II fingerlings to evaluate stocking success at inland stocking locations. Inland stocking locations should be chosen based on potential carrying capacity of phase-II fish and potential trophic interactions with resident species.
3. Elucidate mechanisms affecting natural recruitment. Research stockings of Striped Bass fry should continue to determine if a recruitment bottleneck occurs during the egg development stage.
4. Develop NCWRC Boating Access Areas on the Neuse River upstream of Smithfield. Current access is limited for boat angling and NCWRC field sampling, despite the availability of fish habitat during average to above-average spring streamflow. Two sites have been considered: one near Buffalo Road and one at Anderson Point Park.
5. Replace field data loggers. An upgrade in technology is needed to avoid data loss and improve efficiency of data entry and storage.
6. Develop an age-9+ metric for future data comparisons between sample years.

## Acknowledgments

We thank Edenton National Fish Hatchery staff for hatchery culture and stocking logistics and data compilations associated with our Striped Bass program in the Neuse River. We appreciate cooperation with NC Division of Marine Fisheries. We appreciate cooperation with Dr. Tanya Darden at the SCDNR Hollings Marine Laboratory for processing and analyzing fin clips associated with Striped Bass parentage analysis using microsatellite markers. Suggestions and comments from Kevin Dockendorf, Jeremy McCargo, and Chad Thomas to previous drafts were valued and significantly improved the quality of this report.

[^1]

FIGURE 1. Sampling sites on the Neuse River spawning ground survey. Seven Springs and Kinston sites were not sampled in 2018 and 2019 as these sites are only sampled during extreme low water levels.

FIGURE
2. Length-frequency distributions for Striped Bass collected from the Neuse River, spring 2018 and 2019. Male and female plots sum separately to $100 \%$. Note scale change on y-axis.

FIGURE 3. Composition of hatchery and unknown origin fish by size-class from genetic samples collected during the spring 2018 and 2019 spawning stock survey and broodfish collections. Note scale change on $y$-axis.

[^0]:    This project was funded under the Federal Aid in Sport Fish Restoration Program utilizing state fishing license money and federal grant funds derived from federal excise taxes on fishing tackle and other fishing related expenditures. Funds from the Sport Fish Restoration Program are used for fisheries management and research, aquatic education, and boating access facilities. The program is administered cooperatively by the N.C. Wildlife Resources Commission and the U.S. Fish and Wildlife Service.

[^1]:    ${ }^{a}$ Hatchery staff observed phase II die-off post-stocking; stocking failed.
    ${ }^{\mathrm{b}}$ Broodstock genotypes available.
    ${ }^{\text {c }}$ Neuse River broodstock utilized; Roanoke-source broodstock used 1994-2011.
